# Search for supersymmetry in final states with photons and missing transverse momentum in proton-proton collisions at 13 TeV

## The CMS collaboration

*E-mail:* [cms-publication-committee-chair@cern.ch](mailto:cms-publication-committee-chair@cern.ch)

**ABSTRACT:** Results are reported of a search for supersymmetry in final states with photons and missing transverse momentum in proton-proton collisions at the LHC. The data sample corresponds to an integrated luminosity of  $35.9 \text{ fb}^{-1}$  collected at a center-of-mass energy of 13 TeV using the CMS detector. The results are interpreted in the context of models of gauge-mediated supersymmetry breaking. Production cross section limits are set on gluino and squark pair production in this framework. Gluino masses below 1.86 TeV and squark masses below 1.59 TeV are excluded at 95% confidence level.

**KEYWORDS:** Hadron-Hadron scattering (experiments), Supersymmetry

**1 Introduction**

Supersymmetry (SUSY) and the Minimal Supersymmetric Standard Model [1–6] are extensions of the standard model (SM) that provide explanations for several outstanding issues with the SM. In particular, SUSY addresses the large quantum corrections to the mass term in the Higgs potential [7] and provides a viable dark matter candidate [8, 9]. Models with general gauge-mediated (GGM) SUSY breaking [10–17] have the additional benefit of naturally suppressing flavor violations in the SUSY sector. GGM models can have a wide range of features but typically result in final states that include the gravitino ( $\tilde{G}$ ) as the lightest supersymmetric particle (LSP). The next-to-lightest supersymmetric particle (NLSP) in these models is often taken to be a neutralino ( $\tilde{\chi}_1^0$ ), which is a mixture of the bino, neutral wino, and neutral higgsinos. The conservation of  $R$  parity [18] implies that the gravitino is stable and remains undetected. Therefore, proton-proton (pp) collisions that produce SUSY particles will have an imbalance in the total observed transverse momentum, referred to as missing transverse momentum  $\vec{p}_T^{\text{miss}}$  and defined as the negative vector sum of the transverse momenta of all visible particles in an event. Its magnitude is referred to as  $p_T^{\text{miss}}$ . If the composition of the neutralino NLSP is primarily bino-like, its main decay will be to a gravitino and a photon ( $\gamma$ ), resulting in final states with significant missing transverse momentum and one or more photons.

This paper presents a search for GGM SUSY in final states involving two photons and missing transverse momentum. The data sample, corresponding to an integrated luminosity of  $35.9 \text{ fb}^{-1}$  of pp collisions at a center-of-mass energy  $\sqrt{s} = 13 \text{ TeV}$ , was collected with the CMS detector in 2016. The analysis described here achieves a substantial improvement

**Figure 1.** Diagrams showing the production of signal events in the collision of two protons (p). In gluino ( $\tilde{g}$ ) pair production in the T5gg simplified model (left), the gluino decays to a quark-antiquark pair ( $q\bar{q}$ ) and a neutralino ( $\tilde{\chi}_1^0$ ). In squark ( $\tilde{q}$ ) pair production in the T6gg simplified model (right), the squark decays to a quark and a neutralino. In both cases, the neutralino subsequently decays to a photon ( $\gamma$ ) and a gravitino ( $\tilde{G}$ ).

in sensitivity compared to the search performed by the CMS Collaboration on the smaller 2015 data set [19] and is comparable in sensitivity to similar searches from the ATLAS Collaboration [20, 21].

Two simplified model frameworks [22–26] are used for the interpretation of the results. The T5gg model assumes gluino ( $\tilde{g}$ ) pair production and the T6gg model assumes squark ( $\tilde{q}$ ) pair production. The models assume a 100% branching fraction for the gluinos and squarks to decay as shown in figure 1. The squarks in the T6gg model can be either first or second generation. We assume a 100% branching fraction for the NLSP neutralino to decay to a nearly massless gravitino and a photon,  $\tilde{\chi}_1^0 \rightarrow \tilde{G}\gamma$ , resulting in characteristic events with large  $p_T^{\text{miss}}$  and two photons. In order for the analysis to be as model independent as possible, we choose not to define the signal region using any hadronic variables such as jet multiplicity or the scalar sum of the transverse momentum of the jets.

Standard model processes such as direct diphoton production or events with jets produced through the strong interaction, referred to as quantum chromodynamics (QCD) multijet events, can result in events with two photons. If the hadronic activity in the event is poorly measured, these processes can mimic the signal topology even though they lack genuine  $p_T^{\text{miss}}$ . For the case of QCD multijet events, there may be real photons in the event, or jets rich in electromagnetic (EM) energy that are misreconstructed as photons. Events with genuine  $p_T^{\text{miss}}$  also contribute to the composition of the candidate sample. These events are mainly from  $W\gamma$  and  $W+\text{jet(s)}$  production, where an electron is misidentified as a photon in  $W \rightarrow e\nu$  decays. A smaller background arises from  $Z\gamma\gamma$  events where the  $Z$  boson decays to two neutrinos,  $Z \rightarrow \nu\bar{\nu}$ .

## 2 Detector, data, and simulated samples

The central feature of the CMS apparatus is a superconducting solenoid of 6 m internal diameter, providing a magnetic field of 3.8 T. Within the solenoid volume are a silicon pixel and strip tracker covering the pseudorapidity region  $|\eta| < 2.5$ , as well as a lead tungstate crystal electromagnetic calorimeter (ECAL), and a brass and scintillator hadron calorime-

ter (HCAL), each composed of a barrel and two endcap regions and covering the range  $|\eta| < 3.0$ . Forward calorimeters extend the coverage up to  $|\eta| < 5.0$ . Muons are measured in gas-ionization detectors embedded in the steel flux-return yoke outside the solenoid and cover the range  $|\eta| < 2.4$ . A more detailed description of the CMS detector, together with a definition of the coordinate system used and the relevant kinematic variables, can be found in ref. [27].

Events of interest are selected using a two-tiered trigger system [28]. The first level is composed of custom hardware processors and uses information from the calorimeters and muon detectors to select events at a rate of around 100 kHz. The second level, known as the high-level trigger, consists of a farm of processors running a version of the full event reconstruction software optimized for fast processing. This trigger reduces the event rate to around 1 kHz before data storage. This analysis used a diphoton trigger to collect the data. The trigger requires a leading (subleading) photon with transverse momentum  $p_T > 30$  (18) GeV, and a combined invariant mass  $m_{\gamma\gamma} > 95$  GeV. The photons are also required to pass isolation and cluster shape requirements.

Monte Carlo (MC) simulations are used for several purposes in this analysis. Simulations of the signal processes are used to determine signal efficiencies; background process simulation is used for validation of the analysis performance and to model the contribution from  $Z\gamma\gamma \rightarrow \nu\bar{\nu}\gamma\gamma$  events. The event generator MADGRAPH5\_aMC@NLO 2.3.3 [29] is used to simulate the signal samples at leading order. The background samples are generated at next-to-leading order using MADGRAPH5\_aMC@NLO 2.4.2. For both signal and background processes, the parton showering, hadronization, SUSY particle decays, multiple-parton interactions, and the underlying event are described by the PYTHIA 8.212 [30] program with the CUETP8M1 [31] generator tune. The signal samples are generated with either two gluinos or two squarks and up to two additional partons in the matrix element calculation. The parton distribution functions (PDFs) are obtained from the NNPDF3.0 [32] set. For the background processes, the detector response is simulated using GEANT4 [33], while the CMS fast simulation [34, 35] is used for the signal events. For both signal and background simulated events, additional pp interactions (pileup) are generated with PYTHIA and superimposed on the primary collision process. The simulated events are reweighted to match the pileup distribution observed in data.

The signal events were generated using the T5gg and T6gg simplified models and are characterized by the masses of the particles in the decay chain. For the gluino (squark) mass we simulate a range of values from 1.4 to 2.5 (1.2 to 2.0) TeV in steps of 50 GeV. These mass ranges were selected to overlap and expand upon the mass ranges excluded by previous searches [19, 20]. The neutralino masses range from 10 GeV up to the mass of the gluino or squark. The cross sections are calculated at next-to-leading-order (NLO) accuracy including the resummation of soft gluon emission at next-to-leading-logarithmic (NLL) accuracy [36–40], with all the unconsidered sparticles assumed to be heavy and decoupled. The uncertainties in the cross sections are calculated as described in ref. [41].

### 3 Event selection

Photon, electron, muon, charged and neutral hadron candidates are reconstructed with the particle-flow event algorithm [42], which reconstructs particles based on information from all detector subsystems. The energy of photons is directly obtained from the ECAL measurement. The energy of electrons is determined from a combination of the electron momentum at the primary interaction vertex as determined by the tracker, the energy of the corresponding ECAL cluster, and the energy sum of all bremsstrahlung photons spatially compatible with originating from the electron track. The energy of muons is obtained from the curvature of the corresponding track. The energy of charged hadrons is determined from a combination of their momentum measured in the tracker and the matching ECAL and HCAL energy deposits, corrected for zero-suppression effects and for the response function of the calorimeters to hadronic showers. Finally, the energy of neutral hadrons is obtained from the corresponding corrected ECAL and HCAL energy.

Photon candidates are required to satisfy a series of identification criteria to ensure a high purity [43]. The shape of the energy deposit in the ECAL must be consistent with that of an EM shower, and the amount of energy present in the corresponding region of the HCAL must not exceed 5% of the ECAL energy, since EM showers are expected to be contained almost entirely within the ECAL. To ensure high trigger efficiency, we require all photons to satisfy  $p_T > 40$  GeV. Because the SUSY signal models used in this analysis produce photons primarily in the central region of the detector and because the magnitude of the background increases considerably at high  $|\eta|$ , we consider only photons within the barrel fiducial region of the detector ( $|\eta| < 1.44$ ).

To suppress quark and gluon jets that mimic photons, photon candidates are required to be isolated from other reconstructed particles. Separate requirements are made on the scalar  $p_T$  sums of charged and neutral hadrons and EM objects in a cone of radius  $\Delta R \equiv \sqrt{(\Delta\eta)^2 + (\Delta\phi)^2} \equiv 0.3$  around the photon candidate. Each  $p_T$  sum is corrected for the effect of pileup, and in each case the momentum of the photon candidate itself is excluded. We further require that the photon candidate has no pixel detector track seed, to distinguish the candidate from an electron.

For the purpose of defining the various control regions used in the analysis, we apply an additional set of selection criteria. A misidentified “fake” photon ( $f$ ) is defined as a photon candidate that satisfies looser requirements on photon isolation and neutral-hadron isolation and fails either the shape requirement for the ECAL clusters or the charged-hadron isolation requirement. In order to ensure that misidentified photons do not differ too much from our photon selection, upper limits are applied to both the charged-hadron isolation and cluster shape requirements. Importantly, because of the large amount of hadronic activity expected in our SUSY signal events, it is possible that real photons from the decay of a neutralino could fail the charged-hadron isolation requirement and therefore fall into the misidentified photon category. In order to avoid this potential signal contamination from SUSY events in the control regions, we additionally require that misidentified photons satisfy  $R_9 < 0.9$ , where  $R_9$  is defined as the ratio of the energy deposited in a  $3 \times 3$  array of ECAL crystals to the total energy in the cluster [43]. Real photons have values of  $R_9$

close to unity, so by requiring  $R_9 < 0.9$  we ensure that real photons from a possible SUSY signal will not enter our control regions.

Because of the similarity of the ECAL response to electrons and photons,  $Z \rightarrow ee$  events are used to measure the photon identification efficiency. The selection of electron candidates is identical to that of photons, with the exception that the candidate is required to be matched to a pixel detector seed consistent with a track, to ensure that the electron selection is orthogonal to that of photons. The photon efficiency is measured via the tag-and-probe method [43]. The ratio of the observed to simulated efficiency is found to be consistent with unity and independent of  $p_T$  and  $\eta$ . The efficiency of the pixel detector seed veto for photons is measured in  $Z \rightarrow \mu\mu\gamma$  events and is found to agree between data and simulation.

Events are then assigned to one of four mutually exclusive categories depending on the selection of their highest  $p_T$  EM objects:  $\gamma\gamma$ ,  $ee$ ,  $ff$ , and  $e\gamma$ . The two EM objects are required to be separated by  $\Delta R > 0.6$ . Finally, because of the trigger requirements described in section 2, the invariant mass of the two EM objects is required to be greater than 105 GeV.

In addition to the requirements already described, any event with a muon satisfying  $p_T > 25$  GeV and  $|\eta| < 2.4$  as well as track quality and isolation requirements is vetoed. Similarly, we veto events with any additional electrons satisfying  $p_T > 25$  GeV,  $|\eta| < 2.5$ , and signal shape and isolation requirements.

Events in the candidate  $\gamma\gamma$  sample are divided into the low- $p_T^{\text{miss}}$  control region ( $p_T^{\text{miss}} < 100$  GeV) and the high- $p_T^{\text{miss}}$  signal region ( $p_T^{\text{miss}} > 100$  GeV). The signal region is further divided into six  $p_T^{\text{miss}}$  bins that were chosen such that there is a sufficient number of events from the  $ff$  control sample in each bin.

## 4 Estimation of backgrounds

As described in section 1, there are three primary backgrounds to this analysis. QCD processes such as multijet production can emulate the signal topology if the hadronic activity in the event is mismeasured. A second background arises from electroweak (EWK) processes that have genuine  $p_T^{\text{miss}}$  from the production of neutrinos. There is also a small contribution from  $Z\gamma\gamma \rightarrow \gamma\gamma\nu\bar{\nu}$  events.

The contribution from the QCD background is estimated from the observed data using the  $ff$  control sample. The ratio of the event yield in the candidate  $\gamma\gamma$  sample to that in the  $ff$  sample is constructed as a function of  $p_T^{\text{miss}}$ . More  $ff$  events are observed at high  $p_T^{\text{miss}}$  relative to the  $\gamma\gamma$  sample. Different functional forms were investigated to model the  $p_T^{\text{miss}}$  dependence, and an exponential function was found to describe the data the best. We fit the  $\gamma\gamma$  to  $ff$  ratio in the  $p_T^{\text{miss}} < 100$  GeV control region. The predicted number of QCD background events ( $N_{\text{QCD}}^i$ ) in bin  $i$  of the signal region is then given by the following equation, where  $N_{ff}^i$  is the number of observed  $ff$  events and  $g_{\text{ave}}^i$  is the average value of the fit function  $g(p_T^{\text{miss}})$  in that bin:

$$N_{\text{QCD}}^i = g_{\text{ave}}^i N_{ff}^i \quad (4.1)$$

In order to set a systematic uncertainty on the method, we derive a second QCD background prediction by noting that the  $p_T^{\text{miss}}$  distribution of the  $ff$  control sample is dependent on the  $R_9$  requirement on the misidentified photons. An alternate  $ff$  control sample is built using photon candidates that satisfy all of the requirements for misidentified photons as outlined in section 3, with the exception that the  $R_9$  requirement is reversed. In the  $p_T^{\text{miss}} < 100$  GeV control region, we perform an exponential fit to the ratio of the event yield in the high- $R_9$   $ff$  sample to that of the nominal, low- $R_9$   $ff$  sample. This function ( $h(p_T^{\text{miss}})$ ) represents the correction required to account for the effect of the  $R_9$  selection on the  $p_T^{\text{miss}}$  distribution. The size of the correction is between 20 and 40% in the  $p_T^{\text{miss}} > 100$  GeV signal region. Multiplying the number of low- $R_9$   $ff$  events observed in the signal region by this function gives a proxy high- $R_9$   $ff$  sample.

$$N_{\text{proxy}}^i = h_{\text{ave}}^i N_{ff}^i \quad (4.2)$$

For  $p_T^{\text{miss}} < 100$  GeV, the ratio of the  $p_T^{\text{miss}}$  distribution in the  $\gamma\gamma$  sample to that of the proxy  $ff$  sample is fit to a constant  $C$ . We multiply this constant value by the proxy  $ff$  yield in the signal region to get a second prediction for the QCD background in bin  $i$ .

$$N_{\text{QCD}}^i = C N_{\text{proxy}}^i \quad (4.3)$$

The two background estimation methods give values that are consistent within the uncertainties. All three of the fits used in the two methods are found to represent the data well in the low- $p_T^{\text{miss}}$  control region. Several studies were performed to verify the procedure, including using a mixed- $R_9$   $ff$  sample with one misidentified photon satisfying  $R_9 > 0.9$  and one satisfying  $R_9 < 0.9$  to confirm that the exponential fit continues to accurately describe the mixed- $R_9$   $ff$  to nominal  $ff$  ratio in the high- $p_T^{\text{miss}}$  signal region. As an additional check, a control sample with one photon and one misidentified photon was used as a proxy for the  $\gamma\gamma$  candidate sample in a closure test of the method up to  $p_T^{\text{miss}} = 250$  GeV. At larger values of  $p_T^{\text{miss}}$ , there is the potential for signal contamination in the  $\gamma f$  control sample.

Another background for this analysis comes from EWK processes with genuine  $p_T^{\text{miss}}$ . This background primarily involves  $W\gamma$  and  $W$ +jets events where the  $W$  decays to an electron and a neutrino and the electron is misidentified as photon. This leads to final states with photons and significant  $p_T^{\text{miss}}$ . To obtain an estimate of the EWK background in the signal region, the mass peaks from the  $Z$  boson in the  $ee$  control sample and the  $e\gamma$  control sample are modeled using an extended likelihood fit for the signal plus background hypothesis. The rate at which electrons are misidentified as photons ( $f_{e\rightarrow\gamma}$ ) is calculated using the signal fit integrals  $N_{e\gamma}$  and  $N_{ee}$  for each sample. These can be expressed in terms of the number of true  $Z$  bosons,  $N_Z^{\text{True}}$ :  $N_{ee} = (1 - f_{e\rightarrow\gamma})^2 N_Z^{\text{True}}$  and  $N_{e\gamma} = 2f_{e\rightarrow\gamma}(1 - f_{e\rightarrow\gamma})N_Z^{\text{True}}$ . The factor of 2 in  $N_{e\gamma}$  occurs because either electron in the event could be misidentified as a photon.

Taking the ratio of these two values, we find that the misidentification rate is given by  $f_{e\rightarrow\gamma} = N_{e\gamma}/(2N_{ee} + N_{e\gamma})$ . The misidentification rate is calculated as a function of several kinematic variables, including the vertex multiplicity and  $p_T^{\text{miss}}$  of the event and the  $p_T$  of the EM objects. A 30% uncertainty is applied to cover the observed dependencies. The

$p_T^{\text{miss}}$ bin (GeV)	Expected QCD	Stat. uncert.	Fit uncert.	Cross check uncert.
100 – 115	99.0	+7.2, –6.7	$\pm 1.8$	$\pm 9.9$
115 – 130	32.8	+4.2, –3.7	$\pm 0.7$	$\pm 5.5$
130 – 150	18.8	+3.2, –2.7	$\pm 0.5$	$\pm 4.0$
150 – 185	9.9	+2.3, –1.9	$\pm 0.3$	$\pm 2.8$
185 – 250	3.1	+1.3, –0.9	$\pm 0.1$	$\pm 1.5$
$\geq 250$	1.0	+0.8, –0.5	$\pm 0.1$	$\pm 0.8$

**Table 1.** Event yield and statistical and systematic uncertainties (in numbers of events) of the QCD background estimation for each signal  $p_T^{\text{miss}}$  bin for  $35.9 \text{ fb}^{-1}$  of data at 13 TeV.

final EWK background prediction is given by scaling the number of events in the  $e\gamma$  control sample by the factor  $f_{e\gamma \rightarrow \gamma\gamma} = f_{e \rightarrow \gamma} / (1 - f_{e \rightarrow \gamma}) = (2.6 \pm 0.8)\%$ .

The irreducible  $Z\gamma\gamma$  background is modeled via simulation. A 50% uncertainty is applied to conservatively cover the effects from the statistical uncertainty of the MC sample, the PDF uncertainty in the cross section, NNLO corrections in the simulation, and any other sources of potential mismodeling.

## 5 Sources of systematic uncertainty

Systematic uncertainties are calculated for each contribution to the total background prediction. In addition, systematic uncertainties are assigned for the signal efficiency and the integrated luminosity. The value of each uncertainty and the method used to calculate it are described below.

The largest uncertainties in the background prediction come from uncertainties associated with the QCD background estimate. The magnitude of each uncertainty is shown in table 1 for the six signal bins. The statistical uncertainty from the  $ff$  control sample ranges from 7 to 79% in the signal region. The uncertainty obtained from propagating the errors in the fit parameters to the final prediction is between 2 and 5%. Finally, as described in section 4, a systematic uncertainty in the fitting procedure is calculated by comparing the primary prediction to the cross check prediction derived using the high- $R_9$   $ff$  sample. The systematic uncertainty is taken as the difference between the two methods or the uncertainty in that difference, whichever is larger, and ranges between 10 and 83% in the signal region.

Uncertainties in the EWK background prediction include the statistical uncertainty from the  $e\gamma$  control sample and the 30% uncertainty in the rate at which electrons are misidentified as photons. The statistical uncertainty is less than 9% in each of the six signal bins.

There are also several uncertainties associated with the signal efficiency. The statistical uncertainty from the size of the T5gg or T6gg signal scans ranges from 2 to 44% depending on the mass bin. The PDF uncertainties in the cross sections for signal simulation are between 19 and 35% and are taken from ref. [41]. Other uncertainties include how well the jet energy scale is known (1 to 30%) and the uncertainty in the photon identification efficiency (2.5%). The uncertainty in the integrated luminosity of the data sample is 2.5% [44].

**Figure 2.** The top panel shows the observed  $p_T^{\text{miss}}$  distribution in data (black points) and predicted background distributions prior to the fit described in the text. The vertical line marks the boundary between the control region ( $p_T^{\text{miss}} < 100$  GeV) and the signal region ( $p_T^{\text{miss}} > 100$  GeV). The last bin is the overflow bin and includes all events with  $p_T^{\text{miss}} > 250$  GeV. The QCD background is shown in red, the EWK background is shown in blue, and the  $Z\gamma\gamma$  background is shown in green. The  $p_T^{\text{miss}}$  distribution shown in pink (purple) corresponds to the T5gg simplified model with  $m_{\tilde{g}} = 1700$  (2000) GeV and  $m_{\tilde{\chi}_1^0} = 1000$  GeV. The  $p_T^{\text{miss}}$  distributions from the T6gg simplified model are similar to the T5gg distributions shown here. The bottom panel shows the ratio of observed events to the expected background. The error bars on the ratio correspond to the statistical uncertainty in the number of observed events. The shaded region corresponds to the total uncertainty in the background estimate.

## 6 Results

We determine 95% confidence level (CL) upper limits on gluino pair production and squark pair production cross sections using the modified frequentist  $\text{CL}_s$  method [45, 46]. The test statistic is an LHC-style profile likelihood ratio [47], and its distribution is determined using the asymptotic approximation [48]. The likelihood function is constructed from the background and signal  $p_T^{\text{miss}}$  distributions across the six bins described in section 4. The systematic uncertainties described in section 5 are included in the test statistic as constrained nuisance parameters. Systematic uncertainties which directly affect the yields of processes are assumed to follow a log-normal probability distribution, while statistical uncertainties from the limited size of the control samples and the signal MC samples are modeled using gamma probability distributions.

The full background prediction and the measured  $p_T^{\text{miss}}$  distribution prior to the fit are shown in figure 2. The expected and observed numbers of events for each bin in the signal region are shown in table 2 for the pre-fit distributions and table 3 for the post-fit distributions. Notably, in the last bin we observe 12 events and expect  $5.4_{-1.5}^{+1.6}$  background

$p_T^{\text{miss}}$ bin (GeV)	QCD	EWK	$Z\gamma\gamma$	Total background	Observed
100 – 115	$99 \pm 12$	$13.7 \pm 4.2$	$1.3 \pm 0.6$	$114 \pm 13$	105
115 – 130	$32.8^{+7.0}_{-6.7}$	$9.0 \pm 2.7$	$1.1 \pm 0.6$	$42.9^{+7.5}_{-7.3}$	39
130 – 150	$18.8^{+5.1}_{-4.9}$	$7.4 \pm 2.3$	$1.1 \pm 0.6$	$27.3^{+5.6}_{-5.4}$	21
150 – 185	$9.9^{+3.6}_{-3.4}$	$6.1 \pm 1.9$	$1.3 \pm 0.7$	$17.4^{+4.1}_{-3.9}$	21
185 – 250	$3.1^{+1.9}_{-1.7}$	$5.8 \pm 1.8$	$1.3 \pm 0.6$	$10.2^{+2.7}_{-2.6}$	11
$\geq 250$	$1.0^{+1.1}_{-0.9}$	$3.3 \pm 1.1$	$1.1 \pm 0.6$	$5.4^{+1.6}_{-1.5}$	12

**Table 2.** Number of expected background and observed data events with  $35.9\text{fb}^{-1}$  of 13 TeV data in the signal region prior to the fit defined in the text. The uncertainty in each expected background yield includes the statistical uncertainty and all of the systematic uncertainties described in section 5 added in quadrature.

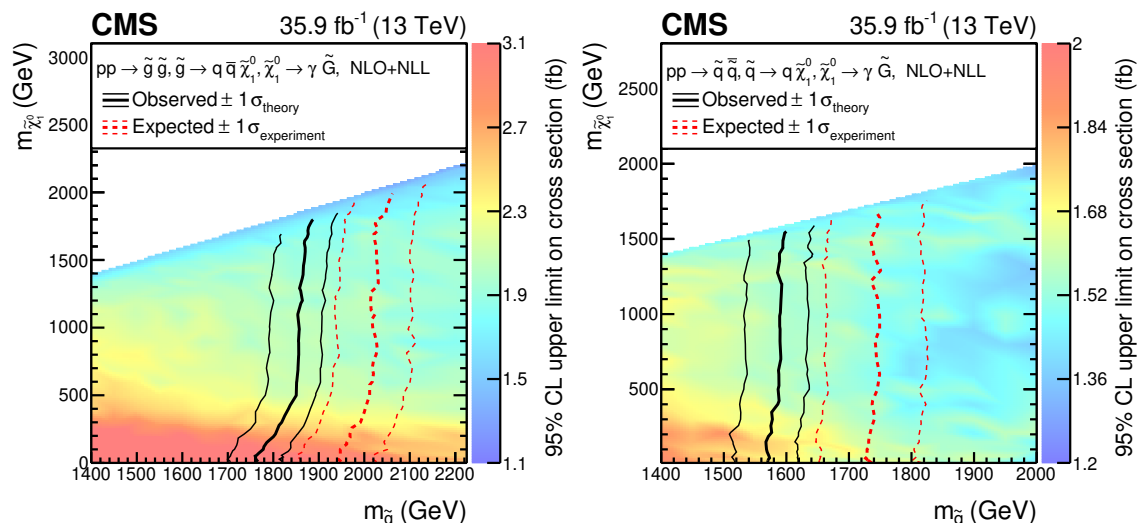

$p_T^{\text{miss}}$ bin (GeV)	QCD	EWK	$Z\gamma\gamma$	Total background	Observed

**Table 3.** Number of expected background and observed data events with  $35.9\text{fb}^{-1}$  of 13 TeV data in the signal region after the fit defined in the text. The stated uncertainties are the post-fit uncertainties in each expected background yield.

events (pre-fit). The significance of the observed data after the fit across all six bins of the signal region is calculated using the likelihood ratio test for each mass pair value of  $m_{\tilde{\chi}_1^0}$  versus  $m_{\tilde{g}}$  or  $m_{\tilde{\chi}_1^0}$  versus  $m_{\tilde{q}}$  for the T5gg and T6gg models, respectively. The significance does not strongly depend on the SUSY masses, and for all masses in both models, the significance is found to correspond to between 2.35 and 2.45 standard deviations. Several studies were performed to characterize the fit and the excess in the final  $p_T^{\text{miss}}$  bin and to ensure that the statistical treatment of the data is robust. In particular, the pre- and postfit distributions were checked to make sure that the pulls are consistent within the uncertainties.

In figure 3 we present 95% CL upper limits on the gluino and squark pair production cross sections as a function of the mass pair values for the two models considered in this analysis. From the NLO+NLL predicted signal cross sections and their uncertainties we derive contours representing lower limits in the SUSY mass plane. We also show expected limit contours based on the expected experimental cross section limits and their uncertainties. For values of the neutralino mass between 500 and 1500 GeV, we expect to exclude gluino masses up to 2.02 TeV and squark masses up to 1.74 TeV. This is an improvement

**Figure 3.** The 95% confidence level upper limits on the gluino (left) and squark (right) pair production cross sections as a function of gluino or squark and neutralino masses. The contours show the observed and expected exclusions assuming the NLO+NLL cross sections, with their one standard deviation uncertainties.

of approximately 400 and 300 GeV, respectively, upon the reach of the previous CMS result [19]. We observe exclusions for gluino masses up to 1.86 TeV and squark masses up to 1.59 TeV. The observed exclusions are lower than the expected exclusions because of the observed excess in the data.

## 7 Summary

The results of a search for general gauge-mediated supersymmetry breaking in proton-proton collisions with two photons and missing transverse momentum in the final state are reported. The analysis was performed using data corresponding to  $35.9 \text{ fb}^{-1}$  of integrated luminosity, recorded with the CMS detector in 2016 at a proton-proton center-of-mass energy of 13 TeV. An excess of events corresponding to 2.4 standard deviations is observed. Limits are determined on the masses of supersymmetric particles in two simplified models using data-driven background estimation methods and NLO+NLL signal cross section calculations.

In both models, the next-to-lightest supersymmetric particle is the neutralino, which decays with a 100% branching fraction to a photon and a gravitino, the lightest supersymmetric particle. The first simplified model assumes gluino pair production, with each gluino decaying to a neutralino and quarks. The second simplified model assumes squark pair production, with each squark decaying to a quark and a neutralino. The expected limits on gluino and squark masses, for the respective models, are 2.02 and 1.74 TeV at 95% confidence level. This is an increase in sensitivity of more than 300 GeV for each model with respect to the analysis performed with  $2.3 \text{ fb}^{-1}$  of integrated luminosity collected using the CMS detector in 2015. The observed exclusions are for gluino masses less than 1.86 TeV

and squark masses less than 1.59 TeV, where the difference between the expected and observed exclusions is driven by the excess observed in the data. The analysis described in this paper improves the observed limits by 210 GeV for gluino masses and 220 GeV for squark masses with respect to the previous CMS result.

## Acknowledgments

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centers and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC and the CMS detector provided by the following funding agencies: BMBWF and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, FAPERGS, and FAPESP (Brazil); MES (Bulgaria); CERN; CAS, MoST, and NSFC (China); COLCIENCIAS (Colombia); MSES and CSF (Croatia); RPF (Cyprus); SENESCYT (Ecuador); MoER, ERC IUT, and ERDF (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); BMBF, DFG, and HGF (Germany); GSRT (Greece); NKFI (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); MSIP and NRF (Republic of Korea); MES (Latvia); LAS (Lithuania); MOE and UM (Malaysia); BUAP, CINVESTAV, CONACYT, LNS, SEP, and UASLP-FAI (Mexico); MOS (Montenegro); MBIE (New Zealand); PAEC (Pakistan); MSHE and NSC (Poland); FCT (Portugal); JINR (Dubna); MON, RosAtom, RAS, RFBR, and NRC KI (Russia); MESTD (Serbia); SEIDI, CPAN, PCTI, and FEDER (Spain); MOSTR (Sri Lanka); Swiss Funding Agencies (Switzerland); MST (Taipei); ThEPCenter, IPST, STAR, and NSTDA (Thailand); TUBITAK and TAEK (Turkey); NASU and SFFR (Ukraine); STFC (United Kingdom); DOE and NSF (U.S.A.).

Individuals have received support from the Marie-Curie program and the European Research Council and Horizon 2020 Grant, contract Nos. 675440 and 765710 (European Union); the Leventis Foundation; the A.P. Sloan Foundation; the Alexander von Humboldt Foundation; the Belgian Federal Science Policy Office; the Fonds pour la Formation à la Recherche dans l'Industrie et dans l'Agriculture (FRIA-Belgium); the Agentschap voor Innovatie door Wetenschap en Technologie (IWT-Belgium); the F.R.S.-FNRS and FWO (Belgium) under the “Excellence of Science — EOS” — be.h project n. 30820817; the Beijing Municipal Science & Technology Commission, No. Z181100004218003; the Ministry of Education, Youth and Sports (MEYS) of the Czech Republic; the Lendület (“Momentum”) Programme and the János Bolyai Research Scholarship of the Hungarian Academy of Sciences, the New National Excellence Program ÚNKP, the NKFI research grants 123842, 123959, 124845, 124850, 125105, 128713, 128786, and 129058 (Hungary); the Council of Science and Industrial Research, India; the HOMING PLUS program of the Foundation for Polish Science, cofinanced from European Union, Regional Development Fund, the Mobility Plus program of the Ministry of Science and Higher Educa-

tion, the National Science Center (Poland), contracts Harmonia 2014/14/M/ST2/00428, Opus 2014/13/B/ST2/02543, 2014/15/B/ST2/03998, and 2015/19/B/ST2/02861, Sonatobis 2012/07/E/ST2/01406; the National Priorities Research Program by Qatar National Research Fund; the Programa Estatal de Fomento de la Investigación Científica y Técnica de Excelencia María de Maeztu, grant MDM-2015-0509 and the Programa Severo Ochoa del Principado de Asturias; the Thalís and Aristeia programs cofinanced by EU-ESF and the Greek NSRF; the Rachadapisek Sompot Fund for Postdoctoral Fellowship, Chulalongkorn University and the Chulalongkorn Academic into Its 2nd Century Project Advancement Project (Thailand); the Welch Foundation, contract C-1845; and the Weston Havens Foundation (U.S.A.).

- 44: Also at Budker Institute of Nuclear Physics, Novosibirsk, Russia
- 45: Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia
- 46: Also at University of Belgrade, Belgrade, Serbia
- 47: Also at INFN Sezione di Pavia <sup>a</sup>, Università di Pavia <sup>b</sup>, Pavia, Italy
- 48: Also at National and Kapodistrian University of Athens, Athens, Greece
- 49: Also at Universität Zürich, Zurich, Switzerland
- 50: Also at Stefan Meyer Institute for Subatomic Physics (SMI), Vienna, Austria
- 51: Also at Adiyaman University, Adiyaman, Turkey
- 52: Also at Sirnak University, SIRNAK, Turkey
- 53: Also at Beykent University, Istanbul, Turkey
- 54: Also at Istanbul Aydin University, Istanbul, Turkey
- 55: Also at Mersin University, Mersin, Turkey
- 56: Also at Piri Reis University, Istanbul, Turkey
- 57: Also at Gaziosmanpasa University, Tokat, Turkey
- 58: Also at Ozyegin University, Istanbul, Turkey
- 59: Also at Izmir Institute of Technology, Izmir, Turkey
- 60: Also at Marmara University, Istanbul, Turkey
- 61: Also at Kafkas University, Kars, Turkey
- 62: Also at Istanbul University, Istanbul, Turkey
- 63: Also at Istanbul Bilgi University, Istanbul, Turkey
- 64: Also at Hacettepe University, Ankara, Turkey
- 65: Also at Rutherford Appleton Laboratory, Didcot, United Kingdom
- 66: Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom
- 67: Also at Monash University, Faculty of Science, Clayton, Australia
- 68: Also at Bethel University, St. Paul, U.S.A.
- 69: Also at Karamanoğlu Mehmetbey University, Karaman, Turkey
- 70: Also at Bingol University, Bingol, Turkey
- 71: Also at Sinop University, Sinop, Turkey
- 72: Also at Mimar Sinan University, Istanbul, Istanbul, Turkey
- 73: Also at Texas A&M University at Qatar, Doha, Qatar
- 74: Also at Kyungpook National University, Daegu, Korea
- 75: Also at University of Hyderabad, Hyderabad, India
